Gabriele Tenucci Assignment 6

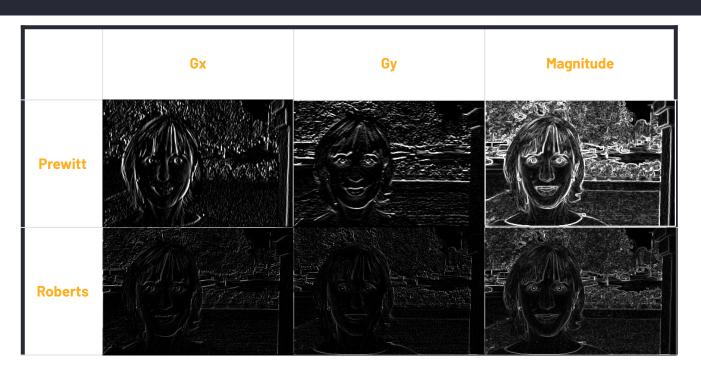

Code

```
for image in images:
#slide over every output cell to calculate its value
                                                                                               print("Elaborating " + image + ".bmp")
  for currentOutRow in range(outRows):
                                                                                               img = cv2.cvtColor(cv2.imread("./" + folder + image + ".bmp"),
    for currentOutCol in range(outCols):
                                                                                                                                       cv2.COLOR_BGR2GRAY)
      #slide over every kernel cell, calculate the current outputcell value
      for currentKerRow in range(kerRows):
                                                                                               #apply filters and save images
        for currentKerCol in range(kerCols):
                                                                                               filterX, filterY = getKernel("sobel")
          rowDiff = currentOutRow - currentKerRow #<---sliding bottom to top
                                                                                               Gx, Gy, magnitude = computeImage(img, filterX, filterY)
                                                                                               saveImage("out", image, "sobel", Gx, Gy, magnitude)
          colDiff = currentOutCol - currentKerCol #<---sliding right to left</pre>
          if (rowDiff >= 0) and (rowDiff < imgRows):</pre>
                                                                                               filterX. filterY = getKernel("prewitt")
             if(colDiff >= 0) and (colDiff < imgCols):</pre>
                                                                                               Gx, Gy, magnitude = computeImage(img, filterX, filterY)
               oldOut = out[currentOutRow, currentOutCol]
                                                                                               saveImage("out", image, "prewitt", Gx, Gy, magnitude)
               currentKer = kernel[currentKerRow, currentKerCol]
               currentImg = image[rowDiff, colDiff]
                                                                                               filterX, filterY = getKernel("roberts")
               out[currentOutRow, currentOutCol] =
                                                                                               Gx. Gv. magnitude = computeImage(img, filterX, filterY)
                                        oldOut + (currentKer * currentImg)
                                                                                               saveImage("out", image, "roberts", Gx, Gy, magnitude)
  return out
```

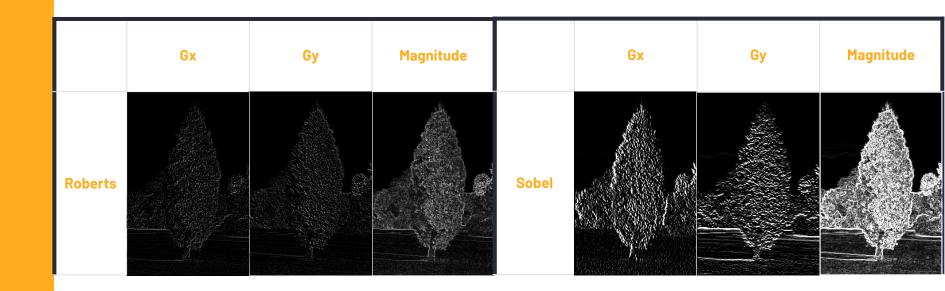

Libraries:

- OpenCV RGB to grayscale conversion, loading and saving images to disk
- Numpy array and matrices manipulations

Applying the filters - face

Applying the filters - tree

More kernels

 $\begin{bmatrix} 0.0625 & 0.125 & 0.0625 \\ 0.125 & 0.25 & 0.125 \\ 0.0625 & 0.125 & 0.0625 \end{bmatrix} \qquad \begin{bmatrix} 0 & -1 & 0 \\ -1 & 5 & -1 \\ 0 & -1 & 0 \end{bmatrix} \qquad \begin{bmatrix} -1 & -1 & -1 \\ -1 & 8 & -1 \\ -1 & -1 & -1 \end{bmatrix}$

Improvements

- Smaller kernels result in darker images
 - Possible solution: output scaling
- Implementing RGB convolutions
- Improving efficiency
 - Matrix multiplication
